**Introduction:** Liver cystic neoplasms are uncommon and vary from benign to overt malignant. Liver cystic metastases are rare. Nasopharyngeal carcinoma (NPC) with liver cystic metastasis is extremely rare.

**Case Report:** Here, we reported a 52-year-old man with liver cystic metastasis from a locally cured NPC. The patient received concurrent chemoradiotherapy (CCRT) for NPC 4 years ago and presented with a 6-month history of upper abdominal fullness and pain. No evidence of local recurrence of NPC. Magnetic resonance imaging of abdomen showed a huge, well-defined, lobulated cystic lesion. Ultrasound-guided liver tumor biopsy was performed. In situ hybridization for EBV-encoded RNAs (EBERs) confirmed the diagnosis of metastatic NPC.

**Discussion:** It is difficult to make a diagnosis in liver cystic neoplasms especially with a rarely reported origin. In our case, we used clinical history and EBERs as a specific marker to make an accurate diagnosis.
